FCDS

Programming I

Lecture 8: Parameters and Return Values

Methods (Remember)

- **What is a Method (a function)?**

  A *subprogram* (set of java statements) used to do a certain task. A method has zero or more inputs (called parameters or arguments), and zero or one output (called return value)

  Inputs (parameters) → Method → Output (return value)

- A method that does not return a value is called **void** method

- So far we have seen static methods that takes *zero inputs* and return *no output (void method)*.

- Today we are going to study a static method that may take *inputs* (parameters) and/or return an *output*

Redundant recipes

- Recipe for baking **20** cookies:
  - Mix the following ingredients in a bowl:
    - **4** cups flour
    - **1** cup butter
    - **1** cup sugar
    - **2** eggs
    - **40** pounds chocolate chips …
  - Place on sheet and Bake for about 10 minutes.

- Recipe for baking **40** cookies:
  - Mix the following ingredients in a bowl:
    - **8** cups flour
    - **2** cups butter
    - **2** cups sugar
    - **4** eggs
    - **80** pounds chocolate chips …
  - Place on sheet and Bake for about 10 minutes.

Parameterized recipe

- Recipe for baking **20** cookies:
  - Mix the following ingredients in a bowl:
    - **4** cups flour
    - **1** cup sugar
    - **2** eggs
    - ...

- Recipe for baking **N** cookies:
  - Mix the following ingredients in a bowl:
    - **N/5** cups flour
    - **N/20** cups butter
    - **N/20** cups sugar
    - **N/10** eggs
    - **2N** bags chocolate chips ...
  - Place on sheet and Bake for about 10 minutes.

- **parameter**: A value that distinguishes similar tasks.

Redundant figures

- Consider the task of printing the following lines/boxes:

```
* * * * * * * * * * * *

* * * * * * *

* * * * * * * * * * * * * * * * * * * * * * * * * * * * * * * * * * *

* * * * * * * * *
*               *
* * * * * * * * *

* * * * *
*       *
*       *
* * * * *
```

A redundant solution

```
public class Stars1 {
    public static void main(String[] args) {
        lineOf13();
        lineOf7();
        lineOf35();
        box10x3();
        box5x4();
    }
    public static void lineOf13() {
        for (int i = 1; i <= 13; i++) {
            System.out.print("*");
        }
        System.out.println();
    }
    public static void lineOf7() {
        for (int i = 1; i <= 7; i++) {
            System.out.print("*");
        }
        System.out.println();
    }
    public static void lineOf35() {
        for (int i = 1; i <= 35; i++) {
            System.out.print("*");
        }
        System.out.println();
    }
    ...
```

- This code is redundant.

- What is a better solution?
  - `line` - A method to draw a line of any number of stars.
  - `box` - A method to draw a box of any size.

Parameterization

- **parameter**: A value passed to a method by its caller.

  - Instead of `lineOf7`, `lineOf13`, write `line` to draw any length.
    - When *declaring* the method, we will state that it requires a parameter for the number of stars.
    - When *calling* the method, we will specify how many stars to draw.

```
        7
main  ------------>  line  ------------>  *******

        13
       ------------>  line  ------------>  *************
```
Declaring a parameter

Stating that a method requires a parameter (argument) in order to run

```
public static void methodName (type paramName) {
    statement(s);
}
```

- Example:

```
public static void sayPassword(int code) {
    System.out.println("The password is: " +
    code);
}
```

  – When `sayPassword` is called, the caller must specify the integer code to print.

Passing a parameter

Calling a method and specifying values for its parameters

methodName (**expression**);

- Example:

```
public static void main(String[] args) {
    sayPassword(42);
    sayPassword(12345);
}
```

Output:

```
The password is 42
The password is 12345
```

Parameters and loops

- A parameter can guide the number of repetitions of a loop.

```
public static void main(String[] args) {
    chant(3);
    chant(7);
}

public static void chant(int times) {
    for (int i = 1; i <= times; i++) {
        System.out.println("Just a
  salad...");
    }
}
```

Common errors

- If a method accepts a parameter, it is illegal to call it without passing any value for that parameter.

```
chant();         // ERROR: parameter
value required
```

- The value passed to a method must be of the correct type.

```
chant(3.7);      // ERROR: must be of
type int
```

Value semantics

- **value semantics**: When primitive variables (`int, double`) are passed as parameters, their values are ***copied***.
    - Modifying the parameter will not affect the variable passed in.

```
public static void main(String[] args) {
    int x = 23;
    strange(x);
    System.out.println("2. x = " + x);
    ...
}
public static void strange(int x) {
    x = x + 1;
    System.out.println("1. x = " + x);
}
```

```
Output:

1. x = 24
2. x = 23
```

Value semantics Example

```java
public class ParameterExample{
    public static void main(String[] args) {
        int x = 17;
        doubleNumber(x);
        System.out.println(x);        ⟶    17
        int number = 42;
        doubleNumber(number);
        System.out.println(number);   ⟶    42
    }

    public static void doubleNumber(int number) {
        System.out.println(number);   ⟶    17  42
        number = number * 2;
        System.out.println(number);   ⟶    34  84
    }
}
```

Factorial – Solution 1

```java
public class Fact{
    public static void main(String[] args) {

        // print factorial of 4
        int n = 4;
        int fact = 1;
        for(int i = 2; i <= n ; i++) {
            fact *= i;
        }
        System.out.println(fact);

        // print factorial of 7
        n = 7;
        fact = 1;
        for(int i = 2; i <= n ; i++) {
            fact *= i;
        }
        System.out.println(fact);

        // print factorial of 9
        n = 9;
        fact = 1;
        for(int i = 2; i <= n ; i++) {
            fact *= i;
        }
        System.out.println(fact);
    }
}
```

Factorial – Solution 2

```java
public static void fact4() {
    int n = 4;
    int fact = 1;
    for(int i = 2; i <= n ; i++) {
        fact *= i;
    }
    System.out.println(fact);
}
```

```java
public static void main(String[] args) {
    fact4();
    fact7();
    fact9();
}
```

```java
public static void fact7() {
    int n = 7;
    int fact = 1;
    for(int i = 2; i <= n ; i++) {
        fact *= i;
    }
    System.out.println(fact);
}
```

```java
public static void fact9() {
    int n = 9;
    int fact = 1;
    for(int i = 2; i <= n ; i++) {
        fact *= i;
    }
    System.out.println(fact);
}
```

Factorial – Solution 3

```java
public class Factorial{

    public static void main(String[] args) {

        fact(4);
        fact(7);
        fact(9);
    }

    public static void fact(int n) {

        int fact = 1;
        for(int i = 2; i <= n ; i++) {
            fact *= i;
        }
        System.out.println(fact);
    }
}
```

Multiple parameters

- A method can accept multiple parameters. (separate by ,)
  - When calling it, you must pass values for each parameter.

- Declaration:
  ```
  public static void methodName (type name, …, type name)
    {
        statement(s);

  }
  ```

- Call:
  ```
  methodName (value,  value,  …,  value);
  ```

Multiple params example

```java
public static void main(String[] args) {
    printNumber(4, 9);
    printNumber(17, 6);
    printNumber(8, 0);
    printNumber(0, 8);
}

public static void printNumber(int number, int count) {
    for (int i = 1; i <= count; i++) {
        System.out.print(number);
    }
    System.out.println();
}
```

Output:

```
444444444
171717171717

00000000
```

"Parameter Mystery" problem

```
public class ParameterMystery {
    public static void main(String[] args) {
        int x = 9;
        int y = 2;
        int z = 5;

        mystery(z, y, x);

        mystery(y, x, z);
    }

    public static void mystery(int x, int z, int y) {
        System.out.println(z + " and " + (y - x));
    }
}
```

5   2   9

2   9   5

Output:
2 and 4

"Parameter Mystery" problem

```
public class ParameterMystery {
    public static void main(String[] args) {
        int x = 9;
        int y = 2;
        int z = 5;

        mystery(z, y, x);

        mystery(y, x, z);
    }

    public static void mystery(int x, int z, int y) {
        System.out.println(z + " and " + (y - x));
    }
}
```

2

9

5

9   5   2

Output:

9 and 3

Strings as parameters

```java
public class StringParameters {
    public static void main(String[] args) {
        sayHello("Marty");

        String teacher = "Bictolia";
        sayHello(teacher);
    }

    public static void sayHello(String name) {
        System.out.println("Welcome, " + name);
    }
}
```
Output:

```
Welcome, Marty
Welcome, Bictolia
```

Return values

Return

- **return**: To send out a value as the result of a method.
  - The opposite of a parameter:
    - Parameters send information *in* from the caller to the method.
    - Return values send information *out* from a method to its caller.
      - A call to the method can be used as part of an expression.

Returning a value

```
public static type methodName(parameters) {
    statements;

    ...

    return expression;
}
```

- Example:

```
// Returns the slope of the line between the given points.
public static double slope(int x1, int y1, int x2, int y2) {
    double dy = y2 - y1;
    double dx = x2 - x1;
    return dy / dx;
}
```

  ▪ slope(1, 3, 5, 11) returns 2.0

Factorial (Sum?)

```java
public class Factorial{

    public static void main(String[] args) {
        int sum = fact(3) + fact(4);
        System.out.println(sum);
    }

    public static int fact(int n) {
        int factorial = 1;
        for(int i = 2; i <= n ; i++) {
            factorial *= i;
        }
        return factorial;
    }
}
```

Return examples

```
// Converts degrees Fahrenheit to Celsius.
public static double fToC(double degreesF) {
    double degreesC = 5.0 / 9.0 * (degreesF - 32);
    return degreesC;
}

// Computes triangle hypotenuse length given its side lengths.
public static double hypotenuse(int a, int b) {
    double c = Math.sqrt(a * a + b * b);
    return c;
}
```

- You can shorten the examples by returning an expression:

```
public static double fToC(double degreesF) {
    return 5.0 / 9.0 * (degreesF - 32);
}
```

Common error: Not storing

- Many students incorrectly think that a `return` statement sends a variable's name back to the calling method.

```
public static void main(String[] args) {
    slope(0, 0, 6, 3);
    System.out.println("The slope is " + result);   // ERROR:
}                                                     // result not defined

public static double slope(int x1, int x2, int y1, int y2) {
    double dy = y2 - y1;
    double dx = x2 - x1;
    double result = dy / dx;
    return result;
}
```

Fixing the common error

- Instead, returning sends the variable's *value* back.
  - The returned value must be stored into a variable or used in an expression to be useful to the caller.

```java
public static void main(String[] args) {
    double s = slope(0, 0, 6, 3);   ✔
    System.out.println("The slope is " + s);   ✔
}

public static double slope(int x1, int x2, int y1, int y2) {
    double dy = y2 - y1;
    double dx = x2 - x1;
    double result = dy / dx;
    return result;
}
```

Fixing the common error
(use the returned value in an expression)

```java
public static void main(String[] args) {
    System.out.println("The slope is " + slope(0, 0, 6, 3)); ✓
}

public static double slope(int x1, int x2, int y1, int y2) {
    double dy = y2 - y1;
    double dx = x2 - x1;
    double result = dy / dx;
    return result;
}
```

Example (CountFactors)

- Write a method **countFactors** that returns the number of factors of an integer.
  - **countFactors(24)** returns 8 because 1, 2, 3, 4, 6, 8, 12, and 24 are factors of 24.

- **Solution**:

```java
// Returns how many factors the given number has.
public static int countFactors(int number) {
    int count = 0;
    for (int i = 1; i <= number; i++) {
        if (number % i == 0) {
            count++;   // i is a factor of number
        }
    }
    return count;
}
```

Returning *boolean* Example (isPrime)

```java
public static boolean isPrime(int n) {
    int factors = 0;
    for (int i = 1; i <= n; i++) {
        if (n % i == 0) {
            factors++;
        }
    }
    if (factors == 2) {
        return true;
    } else {
        return false;
    }
}
```

Can be replaced with

return factors == 2;

- Calls to methods returning `boolean` can be used as tests:

```java
if (isPrime(57)) {
    ...
}
```
